Abstract

The global interlaboratory comparison (IC 2017) on measurements of solid-state lighting (SSL) products with goniophotometers was conducted under the International Energy Agency 4E Solid State Lighting Annex with 36 participating laboratories from 19 countries with a total of 42 goniophotometric instruments including mirror-type, near-field type and source-rotating type goniophotometers. A narrow-beam LED lamp and three different types of LED luminaires, including a street lighting luminaire, were used as comparison artefacts for measurements of 16 different quantities. These included electrical, photometric, and colorimetric quantities, and

Interlaboratory Comparison of Goniophotometers (IC 2017) for measurements of SSL products

- Launched in July 2017.
- 3 types of **LED luminaires** and a **narrow-beam LED lamp** were used as comparison artefacts
- Had **36 labs** participating from **19 countries** with a total of **42 goniophotometers** (gonio-spectroradiometers)
- Three different types of goniophotometer (**mirror-rotating type**, **near-field type**, **source-rotating type**) were accepted
- **CIE S 025** was used as the test method
- The comparison was designed in compliance with ISO/IEC 17043 to serve as a **proficiency test** for SSL testing laboratory accreditation programs

IC 2017 Measurement Quantities

General quantities					Unit	
1	Total luminous flux				lm	
2	Luminous efficacy				lm/W	
3	Active power				W	
4	Root-mean-square (RMS) current (DC current for ART-1)				A	
5	Power factor				1	
6	Chromaticity coordinate (u',v') - spatially averaged				1	
7	Correlated colour temperature (CCT) - spatially averaged				K	
8	Colour rendering index (CRI) R_a - spatially averaged				1	
Goniophotometric quantity						
		ART-1	ART-2	ART-3	ART-4	
9	Luminous intensity distribution, value at (0,0)	X	X	X	X	cd
10	Partial luminous flux (15° cone)	X				lm
11	Centre beam intensity	X				cd
12	Beam angle	X				°
13	Street-side downward flux (Forward light*)				X	lm
14	House-side downward flux (Back light*)				X	lm
15	Upward flux (Uplight*)				X	lm
16	Angular spatial colour uniformity Δ_{uv}	X		X		1

* These quantities (for street lighting luminaire) are defined in IES TM-15.

CIE 2021 Presentation – some slides (Sep. 28, 2021 virtual)

Analysis I – Relative differences comparing all 42 instruments

– An example showing results of all artefacts in one graph –

SDPA: Standard Deviation for Proficiency Assessment
(pre-determined to calculate z' scores in proficiency test)

CIE 2021 Presentation – some slides (Sep. 28, 2021 virtual)

Analysis III Results (3) – Colour quantities-1

Standard deviations of the results

❖ Sphere-spectroradiometer was allowed for measurement of color quantities

Average deviations from the reference value

- Variations appear reasonable
- No notable differences between different goniophotometer types
- Variations for ART-4 with sphere system are high

CIE 2021 Presentation – some slides

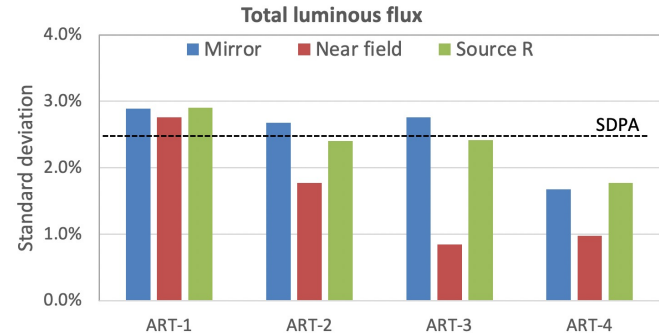

(Sep. 28, 2021 virtual)

Q&A

“Why are the values from the near-field and source rotating gonios more consistent than the mirror ones? I would expect it to be the other way around”

“ What are your conclusions with respect to the revision of CIE S 025?” (CIE D2 Assoc Director)

“how were outliers determined and excluded in standard deviations?”

For improvements of CIE S 025

- Guidance on calculation of gonio quantities
- Guidance on uncertainty evaluation of gonio quantities
- Guidance on mounting and alignment of DUT
- Verification criteria for near-field goniophotometer

Analysis I – Relative differences comparing all 42 instruments

– An example showing results of all artefacts in one graph–

SDPA: Standard Deviation for Proficiency Assessment
(pre-determined to calculate z' scores in proficiency test)

Analysis I – Relative differences comparing all 42 instruments

– An example of results for each artefact –

Error bars: each participant's reported expanded uncertainty ($k=2$)

Range of expanded uncertainty ($k=2$) of Reference value

~60 figures of these were produced for all 16 quantities.

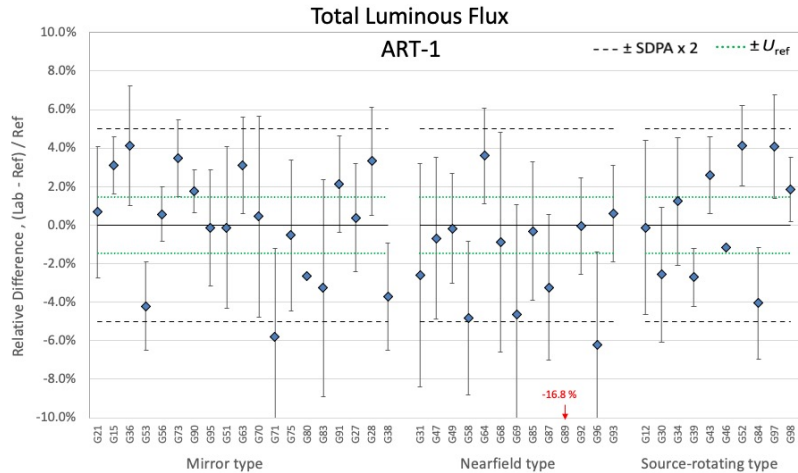

Analysis II – Relative differences sorted by goniophotometer types

– An example of results for each artefact –

~50 figures of these were produced for all 16 quantities.

Analysis III – Standard deviations and Average deviations for each instrument type

Standard deviations of the results for each goniophotometer type

Average deviations (bias) from the reference value for each goniophotometer type

Expanded $U(k=2)$ of Reference value

34 figures of these were produced for all 16 quantities.

Outline

1. Progress since April 2021
2. Presentation of a paper at CIE 2021 Midterm Conference
3. Structure of IC 2017 Final Report
4. Data analysis methodology
- 5. Results and findings**
6. Luminous intensity distributions
7. Summary of Results and Preliminary Recommendations
8. Future activities

Analysis III Results (1) – Photometric quantities

Standard deviations of the results

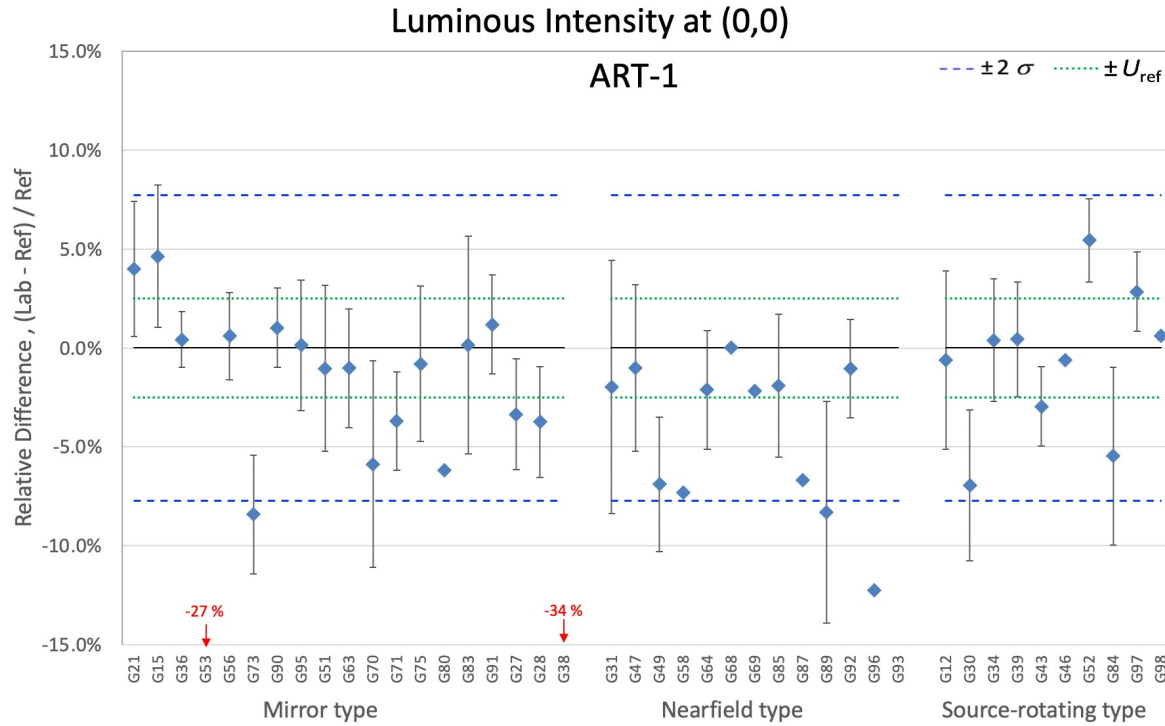

Average deviations from the reference value (bias)

- Total luminous flux: variations appear to be reasonable
- Luminous intensity at (0,0) for ART-1: Near-field type shows notable deviation (negative bias) though this may be still at acceptable uncertainty level

Analysis III Results (1) – Photometric quantities

Analysis III Results (2) – Electrical quantities

Standard deviations of the results

Average deviations from the reference value

- Variations are often much higher than expected (except ART-2)
- Large differences between different artefact types (e.g., power factor)
- Variations of ART-1 are high probably due to small pins and low voltage (DC 12V) thus higher current

Power factor

Analysis III Results (3) – Colour quantities-1

Standard deviations of the results

❖ Sphere-spectroradiometer was allowed for measurement of color quantities

Average deviations from the reference value

- Variations appear reasonable
- No notable differences between different goniophotometer types
- Variations for ART-4 with sphere system are high

Analysis III Results (4) – Colour quantities-2

Standard deviations of the results

Average deviations from the reference value

- Results of CRI R_a appear reasonable
- Colour uniformity: variations are very high, considering that these are relative color measurements

Color uniformity $\Delta u'v'$ (raw results)

Analysis III Results (5) – Goniophotometric quantities (ART-1)

Standard deviations of the results

Average deviations from the reference value

- Center beam intensity: notable negative bias for near-field type, similar to luminous intensity at (0,0)
- partial flux (15° cone angle): Variations are extremely large. It seems many labs calculated 30° cone angle

Extremely large variation in partial luminous flux (15° cone angle) results

← 30° cone angle

Analysis III Results (6) – Goniophotometric quantities (ART-4)

Standard deviations of the results

IES TM-15-11

Average deviations from the reference value

- House-side downward flux:
 - Large variations (4 x than street side) – due to sharp decline of intensity on house side
 - Notable negative bias of near-field type (but uncertainty is also high for this quantity)

Ratios of luminous intensity at (0,0) to centre beam intensity (CBI)

- 21 out of 42 labs reported exactly the same values for $I(0,0)$ and CBI. (Many participants did not calculate CBI as defined)

Results of z' score

Figure 7-156. z' score results for total luminous flux for all artefacts

$|z'| < 2$ satisfactory
 $2 < |z'| < 3$ questionable
 $3 \leq |z'|$ unsatisfactory

Figure 7-160. Percentage of labs that had z' scores outside $-2 \leq z' \leq 2$.

Results of En number

Figure 7-157. E_n number results for total luminous flux for all artefacts

$|E_n| \leq 1$ satisfactory
 $|E_n| > 1$ unsatisfactory

Figure 7-161. Percentage of labs that had E_n numbers outside $-1 \leq E_n \leq 1$.

Analysis IV – Luminous Intensity Distributions

Summary

- Comparisons of LID curves were done only visually because LID data of only four C-planes (0°, 90°, 180°, 270°) were collected from participants.
- More rigorous analyses could have been possible if full LID data had been collected.
- The results of near-field type goniophotometers showed reasonable agreement with the reference lab results (on visual comparison) though ART-1 and ART-4 were considered challenging for near-field goniophotometers.
- The submitted data in many cases did not match with the **C-plane angles** of the reference lab. The C angle rotation was opposite in some cases (CIE coordinate system was not followed) or the origin was different (not following the IC 2017 protocol).
- Comparisons of LID curves for **ART-1 and ART-4** were difficult due to significant variation of **angle alignment of the artefacts**.
- Results of ART-3 revealed **dead angle problems** in upper directions for some goniophotometers. Some source-rotating type goniophotometers are designed for only 2π .
- Some participants reported results in cd/1000 lm (not compliant with CIE S 025).

8. Future activities

Summary of Results

8	SUMMARIES OF RESULTS	146
8.1	COMPARISONS OF 42 INSTRUMENTS.....	146
8.2	COMPARISONS BETWEEN DIFFERENT GONIOPHOTOMETER TYPES	147
8.3	FUTURE IMPROVEMENTS ON TEST METHODS AND GUIDANCE	148

- 8.1**
- Total luminous flux results were mostly within $\pm 5\%$ ($\pm 2 \times$ SDPA) from the reference value, which was an expected level of variation
 - Electrical quantities show some unexpected results. RMS (or DC) current showed much larger variations than expected. The variations of results depended very much on the artefact
 - Color quantities were overall in good agreement
 - Goniophotometric quantities (centre beam intensity, beam angle, partial fluxes, colour uniformity) had larger variations than expected in many cases
 - Some specific problems were identified for 15° cone angle partial flux and beam angle. House-side partial flux had very large variations (due to sensitivity to alignment)
 - Color uniformity showed very large variations and indicated serious problems with some labs.
 - In the result of each quantity, there are often a few outliers with very large deviations, which indicate some mistakes made by the participants. These should be investigated by the participants.

8.2 Comparison between different goniophotometer types

- The differences in results measured by the three different types of goniophotometer were overall insignificant for all the quantities, and both near-field type and source-rotating type goniophotometers that participated in this IC are considered to have equivalent accuracies within typical acceptable uncertainties, for the types of artefacts used in this comparison.
- near-field type goniophotometers for ART-1 (and ART-4) showed notable negative biases for luminous intensity at (0,0) and centre beam intensity, though the magnitude of the deviations is considered an acceptable level. This indicates that the near-field type goniophotometers that participated in IC 2017 had slightly larger uncertainties for very narrow beam or structured intensity distributions.
- The source-rotating type goniophotometers did not show any issues in results, and it rather showed better results for beam angle, colour uniformity, and uplight flux (stray light), than mirror type goniophotometers on the average. (photometric distance can be variable)
- The source-rotating type goniophotometers require correction of results for operating position change of the artefacts per CIE S 025, however, the effects for the artefacts used in this IC were reported to be insignificant. This effect should be investigated for more varieties of products and such correction may not be required for common products by adding an uncertainty component.
- Near-field goniophotometers other than the manufacturer/models used in this comparison also need to be tested.

8.3 Future improvements on test methods and guidance

- Though CIE S 025 refers to CIE 121 for (C, γ) coordinate system, many participants in IC 2017 reported the C angles incorrectly. In some cases direction of rotation is opposite. Giving more guidance will be useful.
- Further guidance is needed on how to calculate **centre beam intensity** and **beam angle** of a beam lamp.
- The definition of beam angle is available in CIE S 025 only for one plane. A further guidance or specification may be needed on how to **determine the beam angle of a lamp**
- More guidance is needed on how to mount and align a narrow-beam lamp to a goniophotometer for the mechanical axis (or optical axis) of the lamp.
- In goniophotometric quantities there were many cases where the participants **did not report uncertainties**. 15 to 20 labs (out of 42 labs) did not report uncertainties for beam angle, centre beam intensity, and partial flux, while only 2 did not report uncertainty for total luminous flux and 5 for colour quantities. Guidance for practical uncertainty evaluation for goniophotometric quantities is needed.
- In CIE S 025, **near-field goniophotometers** are accepted if equivalence to a far-field goniophotometer is demonstrated, but no details and no acceptance criteria are given. It is desired that such criteria will be developed and included in the test method.
- **Source-rotating type goniophotometers** is allowed in CIE S 025 if corrections are applied for the effect of operating position change, however, this type is not allowed in some other regional test methods (e.g., IES LM-79 [10]). Goniophotometers of this type, with appropriate correction, are encouraged as they have big advantage of not requiring a large darkroom space.

Conclusions

- This comparison verified reasonable agreement overall in total luminous flux and chromaticity
- The variations of **electrical quantities** were larger than expected and depended mainly on the comparison artefacts
- This comparison revealed **a number of specific problems** in measurement of **goniophotometric quantities** of SSL products and indicated that more guidance is needed for these measurements
- This comparison also verified that, overall, **near-field type and source-rotating type goniophotometers** used in this comparison **had equivalent accuracies** to far-field goniophotometers for the types of products used in this comparison. (Note: near-field type showed slightly higher uncertainty for a very narrow beam intensity distribution, though it may be within acceptable uncertainty levels)
- Verification in this comparison did **not cover all types of products** in the market and goniophotometric instruments of all manufacturer/models
- The results of this comparison may be useful for **future improvements** in metrology, standards and practice in measurements of SSL products
